How Container/OrganizationalUnit map works on ADC

By Marcelo Calbucci

Keywords: ADC, Containers, OrganizationalUnit,

When replicating from Exchange to AD or vice-versa, you might select Export containers that also have sub-containers on it.

The first attempt ADC will do is try to create a container with the same name under the Import container. Let's use an example:

Your Exchange organization is distributed this way:

+ MyOrg
    + MySite
        + Recipients
            + VIP
            + DLs
            + Misc

So, if you do a map between the container "cn=Recipients,ou=Site,o=MyOrg" to the container "cn=Users,DC=MyDC" on the AD, you should expect that ADC will create the following containers for you:

    + DC=MyDC
        + cn=Users
            + cn=VIP
            + cn=DLs
            + cn=Misc

ADC will only create a sub-container if there is some object under that container to be replicated. This is like copying all files under a directory. If you have something under a subdirectory it will be created, otherwise, why bother?
